

# Security and Privacy Considerations for the OASIS Security Assertion Markup Language (SAML) V1.1

OASIS Standard, 2 September 2003

**Document identifier:**

oasis-sstc-saml-sec-consider-1.1

**Location:**

[http://www.oasis-open.org/committees/documents.php?wg\\_abbrev=security](http://www.oasis-open.org/committees/documents.php?wg_abbrev=security)

**Editor:**

Eve Maler, Sun Microsystems ([eve.maler@sun.com](mailto:eve.maler@sun.com))  
Rob Philpott, RSA Security ([rphilpott@rsasecurity.com](mailto:rphilpott@rsasecurity.com))

**Contributors:**

**Abstract:**

This specification describes and analyzes the security and privacy properties of SAML.

**Status:**

This is an OASIS Standard document produced by the Security Services Technical Committee. It was approved by the OASIS membership on 2 September 2003.

Committee members should submit comments and potential errata to the [security-services@lists.oasis-open.org](mailto:security-services@lists.oasis-open.org) list. Others should submit them to the [security-services-comment@lists.oasis-open.org](mailto:security-services-comment@lists.oasis-open.org) list (to post, you must subscribe; to subscribe, send a message to [security-services-comment-request@lists.oasis-open.org](mailto:security-services-comment-request@lists.oasis-open.org) with "subscribe" in the body) or use other OASIS-supported means of submitting comments. The committee will publish vetted errata on the Security Services TC web page (<http://www.oasis-open.org/committees/security/>).

For information on whether any patents have been disclosed that may be essential to implementing this specification, and any offers of patent licensing terms, please refer to the Intellectual Property Rights web page for the Security Services TC (<http://www.oasis-open.org/committees/security/ipr.php>).

## 100 1 Introduction

101 This non-normative document describes and analyzes the security and privacy properties of the OASIS  
102 Security Assertion Markup Language (SAML) defined in the core SAML specification **[SAMLCore]** and  
103 the SAML specification for bindings and profiles **[SAMLBind]**. The intent in this document is to provide  
104 input to the design of SAML, and to provide information to architects, implementors, and reviewers of  
105 SAML-based systems about the following:

- 106 • The threats, and thus security risks, to which a SAML-based system is subject
- 107 • The security risks the SAML architecture addresses, and how it does so
- 108 • The security risks it does not address
- 109 • Recommendations for countermeasures that mitigate those risks

110 Terms used in this document are as defined in the SAML glossary **[SAMLGloss]** unless otherwise noted.

111 The rest of this section describes the background and assumptions underlying the analysis in this  
112 document. Section 4 provides a high-level view of security techniques and technologies that should be  
113 used with SAML. Section 5 analyzes the specific risks inherent in the use of SAML.

---

## 114 2 Privacy

115 SAML includes the ability to make statements about the attributes and authorizations of authenticated  
116 entities. There are very many common situations in which the information carried in these statements is  
117 something that one or more of the parties to a communication would desire to keep accessible to as  
118 restricted as possible a set of entities. Statements of medical or financial attributes are simple examples  
119 of such cases.

120 Parties making statements, issuing assertions, conveying assertions, and consuming assertions must be  
121 aware of these potential privacy concerns and should attempt to address them in their implementations of  
122 SAML-aware systems.

### 123 2.1 Ensuring Confidentiality

124 Perhaps the most important aspect of ensuring privacy to parties in a SAML-enabled transaction is the  
125 ability to carry out the transaction with a guarantee of confidentiality. In other words, can the information  
126 in an assertion be conveyed from the issuer to the intended audience, and only the intended audience,  
127 without making it accessible to any other parties?

128 It is technically possible to convey information confidentially (a discussion of common methods for  
129 providing confidentiality occurs in the Security portion of the document in Section 4.2). All parties to  
130 SAML-enabled transactions should analyze each of their steps in the interaction to ensure that  
131 information that should be kept confidential is actually being kept so.

132 It should also be noted that simply obscuring the contents of assertions may not be adequate protection  
133 of privacy. There are many cases where just the availability of the information that a given user (or IP  
134 address) was accessing a given service may constitute a breach of privacy (for example, an the  
135 information that a user accessed a medical testing facility for an assertion may be enough to breach  
136 privacy without knowing the contents of the assertion). Partial solutions to these problems can be  
137 provided by various techniques for anonymous interaction, outlined below.

### 138 2.2 Notes on Anonymity

139 The following sections discuss the concept of anonymity.

#### 140 2.2.1 Definitions That Relate to Anonymity

141 There are no definitions of anonymity that are satisfying for all cases. Many definitions **[Anonymity]** deal  
142 with the simple case of a sender and a message, and discuss “anonymity” in terms of not being able to  
143 link a given sender to a sent message, or a message back to a sender.

144 And while that definition is adequate for the “one off” case, it ignores the aggregation of information that is  
145 possible over time based on behavior rather than an identifier.

146 Two notions that may be generally useful, and that relate to each other, can help define anonymity.

147 The first notion is to think about anonymity as being “within a set”, as in this comment from “Anonymity,  
148 Unobservability, and Pseudonymity” **[Anonymity]**:

149       To enable anonymity of a subject, there always has to be an appropriate set of subjects with  
150       potentially the same attributes....

151 ...Anonymity is the stronger, the larger the respective anonymity set is and the more evenly  
152 distributed the sending or receiving, respectively, of the subjects within that set is.

153 This notion is relevant to SAML because of the use of authorities. Even if a Subject is “anonymous”, that  
154 subject is still identifiable as a member of the set of Subjects within the domain of the relevant authority.

155 In the case where aggregating attributes of the user are provided, the set can become much smaller – for  
156 example, if the user is “anonymous” but has the attribute of “student in Course 6@mit.edu”. Certainly, the  
157 number of Course 6 students is less than the number of MIT-affiliated persons which is less than the  
158 number of users everywhere.

159 Why does this matter? Non-anonymity leads to the ability of an adversary to harm, as expressed in  
160 Dingledine, Freedman, and Molnar’s Freehaven document [**FreeHaven**]:

161 Both anonymity and pseudonymity protect the privacy of the user’s location and true name.  
162 Location refers to the actual physical connection to the system. The term “true name” was  
163 introduced by Vinge and popularized by May to refer to the legal identity of an individual.  
164 Knowing someone’s true name or location allows you to hurt him or her.

165 This leads to a unification of the notion of anonymity within a set and ability to harm, from the same  
166 source [**FreeHaven**]:

167 We might say that a system is partially anonymous if an adversary can only narrow down a  
168 search for a user to one of a ‘set of suspects.’ If the set is large enough, then it is impractical  
169 for an adversary to act as if any single suspect were guilty. On the other hand, when the set of  
170 suspects is small, mere suspicion may cause an adversary to take action against all of them.

171 SAML-enabled systems are limited to “partial anonymity” at best because of the use of authorities. An  
172 entity about whom an assertion is made is already identifiable as one of the pool of entities in a  
173 relationship with the issuing authority.

174 The limitations on anonymity can be much worse than simple authority association, depending on how  
175 identifiers are employed, as reuse of pseudonymous identifiers allows accretion of potentially identifying  
176 information (see Section 2.2.2). Additionally, users of SAML-enabled systems can also make the breach  
177 of anonymity worse by their actions (see Section 2.2.3).

## 178 **2.2.2 Pseudonymity and Anonymity**

179 Apart from legal identity, any identifier for a Subject can be considered a pseudonym. And even notions  
180 like “holder of key” can be considered as serving as the equivalent of a pseudonym in linking an action (or  
181 set of actions) to a Subject. Even a description such as “the user that just requested access to object XYZ  
182 at time 23:34” can serve as an equivalent of a pseudonym.

183 Thus, that with respect to “ability to harm,” it makes no difference whether the user is described with an  
184 identifier or described by behavior (for example, use of a key or performance of an action).

185 What does make a difference is how often the particular equivalent of a pseudonym is used.

186 [**Anonymity**] gives a taxonomy of pseudonyms starting from personal pseudonyms (like nicknames) that  
187 are used all the time, through various types of role pseudonyms (such as Secretary of Defense), on to  
188 “one-time-use” pseudonyms.

189 Only one-time-use pseudonyms can give you anonymity (within SAML, consider this as “anonymity within  
190 a set”).

191 The more often you use a given pseudonym, the more you reduce your anonymity and the more likely it is  
192 that you can be harmed. In other words, reuse of a pseudonym allows additional potentially identifying  
193 information to be associated with the pseudonym. Over time, this will lead to an accretion that can  
194 uniquely identify the identity associated with a pseudonym.

## 195 **2.2.3 Behavior and Anonymity**

196 As Joe Klein can attest, anonymity isn't all it is cracked up to be.

197 Klein is the "Anonymous" who authored Primary Colors. Despite his denials he was unmasked as the  
198 author by Don Foster, a Vassar professor who did a forensic analysis of the text of Primary Colors. Foster  
199 compared that text with texts from a list of suspects that he devised based on their knowledge bases and  
200 writing proclivities.

201 It was Klein's idiosyncratic usages that did him in (though apparently all authors have them).

202 The relevant point for SAML is that an "anonymous" user (even one that is never named) can be  
203 identified enough to be harmed by repeated unusual behavior. Here are some examples:

- 204 • A user who each Tuesday at 21:00 access a database that correlates finger lengths and life span  
205 starts to be non-anonymous. Depending on that user's other behavior, she or he may become  
206 "traceable" [**Pooling**] in that other "identifying" information may be able to be collected.
- 207 • A user who routinely buys a usual set of products from a networked vending machine certainly opens  
208 themselves to harm (by virtue of booby-trapping the products).

## 209 **2.2.4 Implications for Privacy**

210 Origin site authorities (such as authentication authorities and attribute authorities) can provide a degree of  
211 "partial anonymity" by employing one-time-use identifiers or keys (for the "holder of key" case).

212 This anonymity is "partial" at best because the Subject is necessarily confined to the set of Subjects in a  
213 relationship with the Authority.

214 This set may be further reduced (thus further reducing anonymity) when aggregating attributes are used  
215 that further subset the user community at the origin site.

216 Users who truly care about anonymity must take care to disguise or avoid unusual patterns of behavior  
217 that could serve to "de-anonymize" them over time.

---

## 218 3 Security

219 The following sections discuss security considerations.

### 220 3.1 Background

221 Communication between computer-based systems is subject to a variety of threats, and these threats  
222 carry some level of associated risk. The nature of the risk depends on a host of factors, including the  
223 nature of the communications, the nature of the communicating systems, the communication mediums,  
224 the communication environment, the end-system environments, and so on. Section 3 of the IETF  
225 guidelines on writing security considerations for RFCs [**Rescorla-Sec**] provides an overview of threats  
226 inherent in the Internet (and, by implication, intranets).

227 SAML is intended to aid deployers in establishing security contexts for application-level computer-based  
228 communications within or between security domains. By serving in this role, SAML addresses the  
229 “endpoint authentication” aspect (in part, at least) of communications security, and also the “unauthorized  
230 usage” aspect of systems security. Communications security is directly applicable to the design of SAML.  
231 Systems security is of interest mostly in the context of SAML’s threat models. Section 2 of the IETF  
232 guidelines gives an overview of communications security and systems security.

### 233 3.2 Scope

234 Some areas that impact broadly on the overall security of a system that uses SAML are explicitly outside  
235 the scope of SAML. While this document does not address these areas, they should always be  
236 considered when reviewing the security of a system. In particular, these issues are important, but  
237 currently beyond the scope of SAML:

- 238 • Initial authentication: SAML allows statements to be made about acts of authentication that have  
239 occurred, but includes no requirements or specifications for these acts of authentication. Consumers  
240 of authentication assertions should be wary of blindly trusting these assertions unless and until they  
241 know the basis on which they were made. Confidence in the assertions must never exceed the  
242 confidence that the asserting party has correctly arrived at the conclusions asserted.
- 243 • Trust Model: In many cases, the security of a SAML conversation will depend on the underlying trust  
244 model, which is typically based on a key management infrastructure (for example, PKI or secret key).  
245 For example, SOAP messages secured by means of XML Signature [**XMLSig**] are secured only  
246 insofar as the keys used in the exchange can be trusted. Undetected compromised keys or revoked  
247 certificates, for example, could allow a breach of security. Even failure to require a certificate opens  
248 the door for impersonation attacks. PKI setup is not trivial and must be implemented correctly in order  
249 for layers built on top of it (such as parts of SAML) to be secure.

### 250 3.3 SAML Threat Model

251 The general Internet threat model described in the IETF guidelines for security considerations [**Rescorla-**  
252 **Sec**] is the basis for the SAML threat model. We assume here that the two or more endpoints of a SAML  
253 transaction are uncompromised, but that the attacker has complete control over the communications  
254 channel.

255 Additionally, due to the nature of SAML as a multi-party authentication and authorization statement  
256 protocol, cases must be considered where one or more of the parties in a legitimate SAML transaction—  
257 who operate legitimately within their role for that transaction—attempt to use information gained from a  
258 previous transaction maliciously in a subsequent transaction.

259 In all cases, the local mechanisms that systems will use to decide whether or not to generate assertions  
260 are out of scope. Thus, threats arising from the details of the original login at an authentication authority,  
261 for example, are out of scope as well. If an authority issues a false assertion, then the threats arising from  
262 the consumption of that assertion by downstream systems are explicitly out of scope.

263 The direct consequence of such a scoping is that the security of a system based on assertions as inputs  
264 is only as good as the security of the system used to generate those assertions. When determining what  
265 issuers to trust, particularly in cases where the assertions will be used as inputs to authentication or  
266 authorization decisions, the risk of security compromises arising from the consumption of false but validly  
267 issued assertions is a large one. Trust policies between asserting and relying parties should always be  
268 written to include significant consideration of liability and implementations must be provide an audit trail.

---

## 269 4 Security Techniques

270 The following sections describe security techniques and various stock technologies available for their  
271 implementation in SAML deployments.

### 272 4.1 Authentication

273 Authentication here means the ability of a party to a transaction to determine the identity of the other party  
274 in the transaction. This authentication may be in one direction or it may be bilateral.

#### 275 4.1.1 Active Session

276 Non-persistent authentication is provided by the communications channel used to transport a SAML  
277 message. This authentication may be unilateral—from the session initiator to the receiver—or bilateral.  
278 The specific method will be determined by the communications protocol used. For instance, the use of a  
279 secure network protocol, such as RFC 2246 [RFC2246] or the IP Security Protocol [IPsec], provides the  
280 SAML message sender with the ability to authenticate the destination for the TCP/IP environment.

#### 281 4.1.2 Message-Level

282 XML Signature [XMLSig] and the OASIS Web Services Security specifications [WSS] provide methods of  
283 creating a persistent “authentication” that is tightly coupled to a document. This method does not  
284 independently guarantee that the sender of the message is in fact that signer (and indeed, in many cases  
285 where intermediaries are involved, this is explicitly not the case).

286 Any method that allows the persistent confirmation of the involvement of a uniquely resolvable entity with  
287 a given subset of an XML message is sufficient to meet this requirement.

### 288 4.2 Confidentiality

289 Confidentiality means that the contents of a message can be read only by the desired recipients and not  
290 anyone else who encounters the message.

#### 291 4.2.1 In Transit

292 Use of a secure network protocol such as RFC 2246 [RFC2246] or the IP Security Protocol [IPsec]  
293 provides transient confidentiality of a message as it is transferred between two nodes.

#### 294 4.2.2 Message-Level

295 XML Encryption [XMLEnc] provides for the selective encryption of XML documents. This encryption  
296 method provides persistent, selective confidentiality of elements within an XML message.

### 297 4.3 Data Integrity

298 Data integrity is the ability to confirm that a given message as received is unaltered from the version of  
299 the message that was sent.

### 300 **4.3.1 In Transit**

301 Use of a secure network protocol such as RFC 2246 [**RFC2246**] or the IP Security Protocol [**IPsec**] may  
302 be configured so as to provide for integrity check CRCs of the packets transmitted via the network  
303 connection.

### 304 **4.3.2 Message-Level**

305 XML Signature [**XMLSig**] provides a method of creating a persistent guarantee of the unaltered nature of  
306 a message that is tightly coupled to that message.

307 Any method that allows the persistent confirmation of the unaltered nature of a given subset of an XML  
308 message is sufficient to meet this requirement.

## 309 **4.4 Notes on Key Management**

310 Many points in this document will refer to the ability of systems to provide authentication, data integrity,  
311 and confidentiality via various schemes involving digital signature and encryption. For all these schemes  
312 the security provided by the scheme is limited based on the key management systems that are in place.  
313 Some specific limitations are detailed below.

### 314 **4.4.1 Access to the Key**

315 It is assumed that, if key-based systems are going to be used for authentication, data integrity, and non-  
316 repudiation, security is in place to guarantee that access to the key is not available to inappropriate  
317 parties. For example, a digital signature created with Bob's private key is only proof of Bob's involvement  
318 to the extent that Bob is the only one with access to the key.

319 In general, access to keys should be kept to the minimum set of entities possible (particularly important  
320 for corporate or organizational keys) and should be protected with passphrases and other means.  
321 Standard security precautions (don't write down the passphrase, when you're away from a computer don't  
322 leave a window with the key accessed open, and so on) apply.

### 323 **4.4.2 Binding of Identity to Key**

324 For a key-based system to be used for authentication there must be some trusted binding of identity to  
325 key. Verifying a digital signature on a document can determine if the document is unaltered since it was  
326 signed, and that it was actually signed by a given key. However, this in no way confirms that the key used  
327 is actually the key of a specific individual.

328 This key-to-individual binding must be established. Common solutions include local directories that store  
329 both identifiers and key—which is simple to understand but difficult to maintain—or the use of certificates.

330 Certificates, which are in essence signed bindings of identity-to-key are a particularly powerful solution to  
331 the problem, but come with their own considerations. A set of trusted root Certifying Authorities (CAs)  
332 must be identified for each consumer of signatures—answering the question “Whom do I trust to make  
333 statements of identity-to-key binding?” Verification of a signature then becomes a process of verifying first  
334 the signature (to determine that the signature was done by the key in question and that the message has  
335 not changed) and then verification of the certificate chain (to determine that the key is bound to the right  
336 identity).

337 Additionally, with certificates steps must be taken to ensure that the binding is currently valid—a  
338 certificate typically has a “lifetime” built into it, but if a key is compromised during the life of the certificate  
339 then the key-to-identity binding contained in the certificate becomes invalid while the certificate is still  
340 valid on its face. Also, certificates often depend on associations that may end before their lifetime expires

341 (for example, certificates that should become invalid when someone changes employers, etc.) This  
342 problem is solved by Certificate Revocation Lists (CRLs), which are lists of certificates from a given CA  
343 that have been revoked since their issue. Another solution is the Online Certificate Status Protocol  
344 (OCSP), which defines a method for calling servers to ask about the current validity of a given certificate.  
345 Some of this same functionality is incorporated into the higher levels of the XML Key Management  
346 Specification [XKMS], which allows requests to be made for "valid" keys.

347 A proper key management system is thus quite strong but very complex. Verifying a signature ends up  
348 being a three-stage process of verifying the document-to-key binding, then verifying the key-to-identity  
349 binding, then verifying the current validity of the key-to-document binding.

## 350 4.5 TLS/SSL Cipher Suites

351 The use of SSL 3.0 or TLS 1.0 [RFC2246] over HTTP is recommended at many places in this document.  
352 However TLS/SSL can be configured to use many different cipher suites, not all of which are adequate to  
353 provide "best practices" security. The following sections provide a brief description of cipher suites and  
354 recommendations for cipher suite selection.

### 355 4.5.1 What Is a Cipher Suite?

356 **Note:** While references to the US Export restrictions are now obsolete, the constants  
357 naming the cipher suites have not changed. Thus,  
358 `SSL_DHE_DSS_EPORT_WITH_DES40_CBC_SHA` is still a valid cipher suite identifier,  
359 and the explanation of the historical reasons for the inclusion of "EXPORT" has been left  
360 in place in the following summary.

361 A cipher suite combines four kinds of security features, and is given a name in the SSL protocol  
362 specification. Before data flows over a SSL connection, both ends attempt to negotiate a cipher suite.  
363 This lets them establish an appropriate quality of protection for their communications, within the  
364 constraints of the particular mechanism combinations which are available. The features associated with a  
365 cipher suite are:

- 366 1. The type of key exchange algorithm used. SSL defines many; the ones that provide server  
367 authentication are the most important ones, but anonymous key exchange is supported. (Note that  
368 anonymous key exchange algorithms are subject to "man in the middle" attacks, and are **not**  
369 **recommended** in the SAML context.) The "RSA" authenticated key exchange algorithm is currently  
370 the most interoperable algorithm. Another important key exchange algorithm is the authenticated  
371 Diffie-Hellman "DHE\_DSS" key exchange, which has no patent-related implementation constraints.<sup>1</sup>
- 372 2. Whether the key exchange algorithm is freely exportable from the United States of America.  
373 Exportable algorithms must use short (512-bit) public keys for key exchange and short (40-bit)  
374 symmetric keys for encryption. These keys are currently subject to breaking in an afternoon by a  
375 moderately well-equipped adversary.
- 376 3. The encryption algorithm used. The fastest option is the RC4 stream cipher; DES and variants  
377 (DES40, 3DES-EDE) are also supported in "cipher block chaining" (CBC) mode, as is null encryption  
378 (in some suites). (Null encryption does nothing; in such cases SSL is used only to authenticate and  
379 provide integrity protection. Cipher suites with null encryption do not provide confidentiality, and  
380 **should not be used** in cases where confidentiality is a requirement.)
- 381 4. The digest algorithm used for the Message Authentication Code. The choices are MD5 and SHA1.

---

<sup>1</sup> The RSA patents have all expired; hence this issue is mostly historical.

382 For example, the cipher suite named SSL\_DHE\_DSS\_EXPORT\_WITH\_DES40\_CBC\_SHA uses SSL,  
383 uses an authenticated Diffie-Hellman key exchange (DHE\_DSS), is export grade (EXPORT), uses an  
384 exportable variant of the DES cipher (DES40\_CBC), and uses the SHA1 digest algorithm in its MAC  
385 (SHA).

386 A given implementation of SSL will support a particular set of cipher suites, and some subset of those will  
387 be enabled by default. Applications have a limited degree of control over the cipher suites that are used  
388 on their connections; they can enable or disable any of the supported cipher suites, but cannot change  
389 the cipher suites that are available.

## 390 **4.5.2 Cipher Suite Recommendations**

391 The following cipher suites adequately meet SAML's requirements for confidentiality and message  
392 integrity, and can be configured to meet the authentication requirement as well (by forcing the presence  
393 of X.509v3 certificates). They are also well supported in many client applications. Support of these suites  
394 is recommended:

- 395 • TLS\_RSA\_WITH\_3DES\_EDE\_CBC\_SHA (when using TLS)
- 396 • SSL\_RSA\_WITH\_3DES\_EDE\_CBC\_SHA (when using SSL)

397 However, the IETF is moving rapidly towards mandating the use of AES, which has both speed and  
398 strength advantages. Forward-looking systems would be wise as well to implement support for the AES  
399 cipher suites, such as:

- 400 • TLS\_RSA\_WITH\_AES\_128\_CBC\_SHA

401

---

## 5 SAML-Specific Security Considerations

402 The following sections analyze the security risks in using and implementing SAML and describe  
403 countermeasures to mitigate the risks.

### 404 5.1 SAML Assertions

405 At the level of the SAML assertion itself, there is little to be said about security concerns—most concerns  
406 arise during communications in the request/response protocol, or during the attempt to use SAML by  
407 means of one of the bindings. The consumer is, of course, always expected to honor the validity interval  
408 of the assertion and any `<DoNotCacheCondition>` elements that are present in the assertion.

409 However, one issue at the assertion level bears analysis: an assertion, once issued, is out of the control  
410 of the issuer. This fact has a number of ramifications. For example, the issuer has no control over how  
411 long the assertion will be persisted in the systems of the consumer; nor does the issuer have control over  
412 the parties with whom the consumer will share the assertion information. These concerns are over and  
413 above concerns about a malicious attacker who can see the contents of assertions that pass over the  
414 wire unencrypted (or insufficiently encrypted).

415 While efforts have been made to address many of these issues within the SAML specification, nothing  
416 contained in the specification will erase the requirement for careful consideration of what to put in an  
417 assertion. At all times, issuers should consider the possible consequences if the information in the  
418 assertion is stored on a remote site, where it can be directly misused, or exposed to potential hackers, or  
419 possibly stored for more creatively fraudulent uses. Issuers should also consider the possibility that the  
420 information in the assertion could be shared with other parties, or even made public, either intentionally or  
421 inadvertently.

### 422 5.2 SAML Protocol

423 The following sections describe security considerations for the SAML request-response protocol itself,  
424 apart from any threats arising from use of a particular protocol binding.

#### 425 5.2.1 Denial of Service

426 The SAML protocol is susceptible to a denial of service (DOS) attack. Handling a SAML request is  
427 potentially a very expensive operation, including parsing the request message (typically involving  
428 construction of a DOM tree), database/assertion store lookup (potentially on an unindexed key),  
429 construction of a response message, and potentially one or more digital signature operations. Thus, the  
430 effort required by an attacker generating requests is much lower than the effort needed to handle those  
431 requests.

##### 432 5.2.1.1 Requiring Client Authentication at a Lower Level

433 Requiring clients to authenticate at some level below the SAML protocol level (for example, using the  
434 SOAP over HTTP binding, with HTTP over TLS/SSL, and with a requirement for client-side certificates  
435 that have a trusted Certificate Authority at their root) will provide traceability in the case of a DOS attack.

436 If the authentication is used only to provide traceability, then this does not in itself prevent the attack from  
437 occurring, but does function as a deterrent.

438 If the authentication is coupled with some access control system, then DOS attacks from non-insiders is  
439 effectively blocked. (Note that it is possible that overloading the client-authentication scheme could still  
440 function as a denial-of-service attack on the SAML service, but that this attack needs to be dealt with in  
441 the context of the client authentication scheme chosen.)

442 Whatever system of client authentication is used, it should provide the ability to resolve a unique  
443 originator for each request, and should not be subject to forgery. (For example, in the traceability-only  
444 case, logging the IP address is insufficient since this information can easily be spoofed.)

### 445 **5.2.1.2 Requiring Signed Requests**

446 In addition to the benefits gained from client authentication discussed in Section 5.2.1.1, requiring a  
447 signed request also lessens the order of the asymmetry between the work done by requester and  
448 responder. The additional work required of the responder to verify the signature is a relatively small  
449 percentage of the total work required of the responder, while the process of calculating the digital  
450 signature represents a relatively large amount of work for the requester. Narrowing this asymmetry  
451 decreases the risk associated with a DOS attack.

452 Note, however, that an attacker can theoretically capture a signed message and then replay it continually,  
453 getting around this requirement. This situation can be avoided by requiring the use of the XML Signature  
454 element `<ds:SignatureProperties>` containing a timestamp; the timestamp can then be used to  
455 determine if the signature is recent. In this case, the narrower the window of time after issue that a  
456 signature is treated as valid, the higher security you have against replay denial of service attacks.

### 457 **5.2.1.3 Restricting Access to the Interaction URL**

458 Limiting the ability to issue a request to a SAML service at a very low level to a set of known parties  
459 drastically reduces the risk of a DOS attack. In this case, only attacks originating from within the finite set  
460 of known parties are possible, greatly decreasing exposure both to potentially malicious clients and to  
461 DOS attacks using compromised machines as zombies.

462 There are many possible methods of limiting access, such as placing the SAML responder inside a  
463 secured intranet and implementing access rules at the router level.

## 464 **5.3 SAML Protocol Bindings**

465 The security considerations in the design of the SAML request-response protocol depend to a large  
466 extent on the particular protocol binding (as defined in the SAML bindings specification **[SAMLBind]**) that  
467 is used. Currently the only binding sanctioned by the OASIS Security Services Technical Committee is  
468 the SOAP binding.

### 469 **5.3.1 SOAP Binding**

470 Since the SAML SOAP binding requires no authentication and has no requirements for either in-transit  
471 confidentiality or message integrity, it is open to a wide variety of common attacks, which are detailed in  
472 the following sections. General considerations are discussed separately from considerations related to  
473 the SOAP-over-HTTP case.

#### 474 **5.3.1.1 Eavesdropping**

475 Since there is no in-transit confidentiality requirement, it is possible that an eavesdropping party could  
476 acquire both the SOAP message containing a request and the SOAP message containing the  
477 corresponding response. This acquisition exposes both the nature of the request and the details of the  
478 response, possibly including one or more assertions.

479 Exposure of the details of the request will in some cases weaken the security of the requesting party by  
480 revealing details of what kinds of assertions it requires, or from whom those assertions are requested. For  
481 example, if an eavesdropper can determine that site *X* is frequently requesting authentication assertions  
482 with a given confirmation method from site *Y*, he may be able to use this information to aid in the  
483 compromise of site *X*.

484 Similarly, eavesdropping on a series of authorization queries could create a “map” of resources that are  
485 under the control of a given authorization authority.

486 Additionally, in some cases exposure of the request itself could constitute a violation of privacy. For  
487 example, eavesdropping on a query and its response may expose that a given user is active on the  
488 querying site, which could be information that should not be divulged in cases such as medical  
489 information sites, political sites, and so on. Also the details of any assertions carried in the response may  
490 be information that should be kept confidential. This is particularly true for responses containing attribute  
491 assertions; if these attributes represent information that should not be available to entities not party to the  
492 transaction (credit ratings, medical attributes, and so on), then the risk from eavesdropping is high.

493 In cases where any of these risks is a concern, the countermeasure for eavesdropping attacks is to  
494 provide some form of in-transit message confidentiality. For SOAP messages, this confidentiality can be  
495 enforced either at the SOAP level or at the SOAP transport level (or some level below it).

496 Adding in-transit confidentiality at the SOAP level means constructing the SOAP message such that,  
497 regardless of SOAP transport, no one but the intended party will be able to access the message. The  
498 general solution to this problem is likely to be XML Encryption [**XMLEnc**]. This specification allows  
499 encryption of the SOAP message itself, which eliminates the risk of eavesdropping unless the key used in  
500 the encryption has been compromised. Alternatively, deployers can depend on the SOAP transport layer,  
501 or a layer beneath it, to provide in-transit confidentiality.

502 The details of how to provide this confidentiality depend on the specific SOAP transport chosen. Using  
503 HTTP over TLS/SSL (described further in Section 5.3.2) is one method. Other transports will necessitate  
504 other in-transit confidentiality techniques; for example, an SMTP transport might use S/MIME.

505 In some cases, a layer beneath the SOAP transport might provide the required in-transit confidentiality.  
506 For example, if the request-response interaction is carried out over an IPsec tunnel, then adequate in-  
507 transit confidentiality may be provided by the tunnel itself.

### 508 **5.3.1.2 Replay**

509 There is little vulnerability to replay attacks at the level of the SOAP binding. Replay is more of an issue in  
510 the various profiles. The primary concern about replay at the SOAP binding level is the potential for use of  
511 replay as a denial-of-service attack method.

512 In general, the best way to prevent replay attacks is to prevent the message capture in the first place.  
513 Some of the transport-level schemes used to provide in-transit confidentiality will accomplish this goal.  
514 For example, if the SAML request-response conversation occurs over SOAP on HTTP/TLS, third parties  
515 are prevented from capturing the messages.

516 Note that since the potential replayer does not need to understand the message to replay it, schemes  
517 such as XML Encryption do not provide protection against replay. If an attacker can capture a SAML  
518 request that has been signed by the requester and encrypted to the responder, then the attacker can  
519 replay that request at any time without needing to be able to undo the encryption. The SAML request  
520 includes information about the issue time of the request, allowing a determination about whether replay is  
521 occurring. Alternatively, the unique key of the request (its *RequestID*) can be used to determine if this is  
522 a replay request or not.

523 Additional threats from the replay attack include cases where a “charge per request” model is in place.  
524 Replay could be used to run up large charges on a given account.

525 Similarly, models where a client is allocated (or purchases) a fixed number of interactions with a system,  
526 the replay attack could exhaust these uses unless the issuer is careful to keep track of the unique key of  
527 each request.

### 528 **5.3.1.3 Message Insertion**

529 The message insertion attack for the SOAP binding amounts to the creation of a request. The ability to  
530 make a request is not a threat at the SOAP binding level.

### 531 **5.3.1.4 Message Deletion**

532 The message deletion attack would either prevent a request from reaching a responder, or would prevent  
533 the response from reaching the requester.

534 In either case, the SOAP binding does not address this threat. The SOAP protocol itself, and the  
535 transports beneath it, may provide some information depending on how the message deletion is  
536 accomplished.

537 Examples of reliable messaging systems that attenuate this risk include reliable HTTP (HTTPR) [HTTPR]  
538 at the transport layer and the use of reliable messaging extensions in SOAP such as Microsoft's SRMP  
539 for MSMQ [SRMPPres].

### 540 **5.3.1.5 Message Modification**

541 Message modification is a threat to the SOAP binding in both directions.

542 Modification of the request to alter the details of the request can result in significantly different results  
543 being returned, which in turn can be used by a clever attacker to compromise systems depending on the  
544 assertions returned. For example, altering the list of requested attributes in the  
545 <AttributeDesignator> elements could produce results leading to compromise or rejection of the  
546 request by the responder.

547 Modification of the request to alter the apparent issuer of the request could result in denial of service or  
548 incorrect routing of the response. This alteration would need to occur below the SAML level and is thus  
549 out of scope.

550 Modification of the response to alter the details of the assertions therein could result in vast degrees of  
551 compromise. The simple examples of altering details of an authentication or an authorization decision  
552 could lead to very serious security breaches.

553 In order to address these potential threats, a system that guarantees in-transit message integrity must be  
554 used. The SAML protocol and the SOAP binding neither require nor forbid the deployment of systems that  
555 guarantee in-transit message integrity, but due to this large threat, it is **highly recommended** that such a  
556 system be used. At the SOAP binding level, this can be accomplished by digitally signing requests and  
557 responses with a system such as XML Signature [XMLSig]. The SAML specification allows for such  
558 signatures; see the SAML assertion and protocol specification [SAMLCore] for further information.

559 If messages are digitally signed (with a sensible key management infrastructure, see Section 4.4) then  
560 the recipient has a guarantee that the message has not been altered in transit, unless the key used has  
561 been compromised.

562 The goal of in-transit message integrity can also be accomplished at a lower level by using a SOAP  
563 transport that provides the property of guaranteed integrity, or is based on a protocol that provides such a  
564 property. SOAP over HTTP over TLS/SSL is a transport that would provide such a guarantee.

565 Encryption alone does not provide this protection, as even if the intercepted message could not be altered  
566 per se, it could be replaced with a newly created one.

### 567 **5.3.1.6 Man-in-the-Middle**

568 The SOAP binding is susceptible to man-in-the-middle (MITM) attacks. In order to prevent malicious  
569 entities from operating as a man in the middle (with all the perils discussed in both the eavesdropping and  
570 message modification sections), some sort of bilateral authentication is required.

571 A bilateral authentication system would allow both parties to determine that what they are seeing in a  
572 conversation actually came from the other party to the conversation.

573 At the SOAP binding level, this goal could also be accomplished by digitally signing both requests and  
574 responses (with all the caveats discussed in Section 5.3.1.5 above). This method does not prevent an  
575 eavesdropper from sitting in the middle and forwarding both ways, but he is prevented from altering the  
576 conversation in any way without being detected.

577 Since many applications of SOAP do not use sessions, this sort of authentication of author (as opposed  
578 to authentication of sender) may need to be combined with information from the transport layer to confirm  
579 that the sender and the author are the same party in order to prevent a weaker form of "MITM as  
580 eavesdropper".

581 Another implementation would depend on a SOAP transport that provides, or is implemented on a lower  
582 layer that provides, bilateral authentication. The example of this is again SOAP over HTTP over TLS/SSL  
583 with both server- and client-side certificates required.

584 Additionally, the validity interval of the assertions returned functions as an adjustment on the degree of  
585 risk from MITM attacks. The shorter the valid window of the assertion, the less damage can be done if it is  
586 intercepted.

### 587 **5.3.2 Specifics of SOAP over HTTP**

588 Since the SOAP binding requires that conformant applications support HTTP over TLS/SSL with a  
589 number of different bilateral authentication methods such as Basic over server-side SSL and certificate-  
590 backed authentication over server-side SSL, these methods are always available to mitigate threats in  
591 cases where other lower-level systems are not available and the above listed attacks are considered  
592 significant threats.

593 This does not mean that use of HTTP over TLS with some form of bilateral authentication is mandatory. If  
594 an acceptable level of protection from the various risks can be arrived at through other means (for  
595 example, by an IPsec tunnel), full TLS with certificates is not required. However, in the majority of cases  
596 for SOAP over HTTP, using HTTP over TLS with bilateral authentication will be the appropriate choice.

597 Note, however, that the use of transport-level security (such as the SSL or TLS protocols under HTTP)  
598 only provides confidentiality and/or integrity and/or authentication for "one hop". For models where there  
599 may be intermediaries, or the assertions in question need to live over more than one hop, the use of  
600 HTTP with TLS/SSL does not provide adequate security.

## 601 **5.4 Profiles of SAML**

602 The SAML bindings specification [**SAMLEndpoint**] in addition defines profiles of SAML, which are sets of  
603 rules describing how to embed SAML assertions into and extract them from a framework or protocol.  
604 Currently there are two profiles for SAML that are sanctioned by the OASIS Security Services Technical  
605 Committee:

- 606 • Two web browser-based profiles that support single sign-on (SSO):
  - 607 – The browser/artifact profile for SAML
  - 608 – The browser/POST profile for SAML

609 (The OASIS Web Services Security Technical Committee has produced another profile of SAML, a draft  
610 "SAML token profile" of the WSS specification [**WSS-SAML**] that describes how to use SAML assertions  
611 to secure a web service message.)

## 612 **5.4.1 Web Browser-Based Profiles**

613 The following sections describe security considerations that are common to the browser/artifact and  
614 browser/POST profiles for SAML.

615 Note that user authentication at the source site is explicitly out of scope, as are all issues that arise from  
616 it. The key notion is that the source system entity must be able to ascertain that the authenticated client  
617 system entity that it is interacting with is the same as the one in the next interaction step. One way to  
618 accomplish this is for these initial steps to be performed using TLS as a session layer underneath the  
619 protocol being used for this initial interaction (likely HTTP).

### 620 **5.4.1.1 Eavesdropping**

621 The possibility of eavesdropping exists in all web browser cases. In cases where confidentiality is  
622 required (bearing in mind that any assertion that is not sent securely, along with the requests associated  
623 with it, is available to the malicious eavesdropper), HTTP traffic needs to take place over a transport that  
624 ensures confidentiality. HTTP over TLS/SSL [**RFC2246**] and the IP Security Protocol [**IPsec**] meet this  
625 requirement.

626 The following sections provide more detail on the eavesdropping threat.

#### 627 **5.4.1.1.1 Theft of the User Authentication Information**

628 In the case where the subject authenticates to the source site by revealing authentication information, for  
629 example, in the form of a password, theft of the authentication information will enable an adversary to  
630 impersonate the subject.

631 In order to avoid this problem, the connection between the subject's browser and the source site must  
632 implement a confidentiality safeguard. In addition, steps must be taken by either the subject or the  
633 destination site to ensure that the source site is genuinely the expected and trusted source site before  
634 revealing the authentication information. Using HTTP over TLS can be used to address this concern.

#### 635 **5.4.1.1.2 Theft of the Bearer Token**

636 In the case where the authentication assertion contains the assertion bearer's authentication protocol  
637 identifier, theft of the artifact will enable an adversary to impersonate the subject.

638 Each of the following methods decreases the likelihood of this happening:

- 639 • The destination site implements a confidentiality safeguard on its connection with the subject's  
640 browser.
- 641 • The subject or destination site ensures (out of band) that the source site implements a confidentiality  
642 safeguard on its connection with the subject's browser.
- 643 • The destination site verifies that the subject's browser was directly redirected by a source site that  
644 directly authenticated the subject.
- 645 • The source site refuses to respond to more than one request for an assertion corresponding to the  
646 same assertion ID.

- 647 • If the assertion contains a condition element of type **AudienceRestrictionConditionType** that  
648 identifies a specific domain, then the destination site verifies that it is a member of that domain.
- 649 • The connection between the destination site and the source site, over which the assertion ID is  
650 passed, is implemented with a confidentiality safeguard.
- 651 • The destination site, in its communication with the source site, over which the assertion ID is passed,  
652 must verify that the source site is genuinely the expected and trusted source site.

### 653 **5.4.1.2 Replay**

654 The possibility of a replay attack exists for this set of profiles. A replay attack can be used either to  
655 attempt to deny service or to retrieve information fraudulently. The specific countermeasures depend on  
656 which specific profile is being used, and thus are discussed in Sections 5.4.2.1 and 5.4.3.1.

### 657 **5.4.1.3 Message Insertion**

658 Message insertion attacks are not a general threat in this set of profiles.

### 659 **5.4.1.4 Message Deletion**

660 Deleting a message during any step of the interactions between the browser, SAML assertion issuer, and  
661 SAML assertion consumer will cause the interaction to fail. It results in a denial of some service but does  
662 not increase the exposure of any information.

663 The SAML bindings and profiles specification provides no countermeasures for message deletion.

### 664 **5.4.1.5 Message Modification**

665 The possibility of alteration of the messages in the stream exists for this set of profiles. Some potential  
666 undesirable results are as follows:

- 667 • Alteration of the initial request can result in rejection at the SAML issuer, or creation of an artifact  
668 targeted at a different resource than the one requested
- 669 • Alteration of the artifact can result in denial of service at the SAML consumer.
- 670 • Alteration of the assertions themselves while in transit could result in all kinds of bad results (if they  
671 are unsigned) or denial of service (if they are signed and the consumer rejects them).

672 To avoid message modification, the traffic needs to be transported by means of a system that guarantees  
673 message integrity from endpoint to endpoint.

674 For the web browser-based profiles, the recommended method of providing message integrity in transit is  
675 the use of HTTP over TLS/SSL with a cipher suite that provides data integrity checking.

### 676 **5.4.1.6 Man-in-the-Middle**

677 Man-in-the-middle attacks are particularly pernicious for this set of profiles. The MITM can relay requests,  
678 capture the returned assertion (or artifact), and relay back a false one. Then the original user cannot  
679 access the resource in question, but the MITM can do so using the captured resource.

680 Preventing this threat requires a number of countermeasures. First, using a system that provides strong  
681 bilateral authentication will make it much more difficult for a MITM to insert himself into the conversation.

682 However the possibility still exists of a MITM who is purely acting as a bidirectional port forwarder, and  
683 eavesdropping on the information with the intent to capture the returned assertion or handler (and  
684 possibly alter the final return to the requester). Putting a confidentiality system in place will prevent  
685 eavesdropping. Putting a data integrity system in place will prevent alteration of the message during port  
686 forwarding.

687 For this set of profiles, all the requirements of strong bilateral session authentication, confidentiality, and  
688 data integrity can be met by the use of HTTP over TLS/SSL if the TLS/SSL layer uses an appropriate  
689 cipher suite (strong enough encryption to provide confidentiality, and supporting data integrity) and  
690 requires X509v3 certificates for authentication.

## 691 **5.4.2 Browser/Artifact Profile**

692 Many specific threats and counter-measures for the Browser/Artifact profile are documented normatively  
693 in the SAML bindings specification **[SAMLBind]**. Additional non-normative comments are included below.

### 694 **5.4.2.1 Replay**

695 The threat of replay as a reuse of an artifact is addressed by the requirement that each artifact is a one-  
696 time-use item. Systems should track cases where multiple requests are made referencing the same  
697 artifact, as this situation may represent intrusion attempts.

698 The threat of replay on the original request that results in the assertion generation is not addressed by  
699 SAML, but should be mitigated by the original authentication process.

## 700 **5.4.3 Browser/POST Profile**

701 Many specific threats and counter-measures for the Browser/POST profile are documented normatively in  
702 the SAML bindings specification **[SAMLBind]**. Additional non-normative comments are included below.

### 703 **5.4.3.1 Replay**

704 Replay attacks amount to resubmission of the form in order to access a protected resource fraudulently.  
705 The profile mandates that the assertions transferred have the one-use property at the destination site,  
706 preventing replay attacks from succeeding.

707

## 760 **Appendix A. Acknowledgments**

761 The editors would like to acknowledge the contributions of the OASIS SAML Technical Committee, whose  
762 voting members at the time of publication were:

- 763 • Frank Siebenlist, Argonne National Laboratory
- 764 • Irving Reid, Baltimore Technologies
- 765 • Hal Lockhart, BEA Systems
- 766 • Steven Lewis, Booz Allen Hamilton
- 767 • John Hughes, Entegriety Solutions
- 768 • Carlisle Adams, Entrust
- 769 • Jason Rouault, Hewlett-Packard
- 770 • Maryann Hondo, IBM
- 771 • Anthony Nadalin, IBM
- 772 • Scott Cantor, individual
- 773 • RL “Bob” Morgan, individual
- 774 • Trevor Perrin, individual
- 775 • Padraig Moloney, NASA
- 776 • Prateek Mishra, Netegrity (co-chair)
- 777 • Frederick Hirsch, Nokia
- 778 • Senthil Sengodan, Nokia
- 779 • Timo Skytta, Nokia
- 780 • Charles Knouse, Oblix
- 781 • Steve Anderson, OpenNetwork
- 782 • Simon Godik, Overxeer
- 783 • Rob Philpott, RSA Security (co-chair)
- 784 • Dipak Chopra, SAP
- 785 • Jahan Moreh, Sigaba
- 786 • Bhavna Bhatnagar, Sun Microsystems
- 787 • Jeff Hodges, Sun Microsystems
- 788 • Eve Maler, Sun Microsystems (coordinating editor)
- 789 • Emily Xu, Sun Microsystems
- 790 • Phillip Hallam-Baker, VeriSign

## Appendix B. Notices

792 OASIS takes no position regarding the validity or scope of any intellectual property or other rights that  
793 might be claimed to pertain to the implementation or use of the technology described in this document or  
794 the extent to which any license under such rights might or might not be available; neither does it  
795 represent that it has made any effort to identify any such rights. Information on OASIS's procedures with  
796 respect to rights in OASIS specifications can be found at the OASIS website. Copies of claims of rights  
797 made available for publication and any assurances of licenses to be made available, or the result of an  
798 attempt made to obtain a general license or permission for the use of such proprietary rights by  
799 implementors or users of this specification, can be obtained from the OASIS Executive Director.

800 OASIS invites any interested party to bring to its attention any copyrights, patents or patent applications,  
801 or other proprietary rights which may cover technology that may be required to implement this  
802 specification. Please address the information to the OASIS Executive Director.

803 **Copyright © OASIS Open 2003. All Rights Reserved.**

804 This document and translations of it may be copied and furnished to others, and derivative works that  
805 comment on or otherwise explain it or assist in its implementation may be prepared, copied, published  
806 and distributed, in whole or in part, without restriction of any kind, provided that the above copyright notice  
807 and this paragraph are included on all such copies and derivative works. However, this document itself  
808 may not be modified in any way, such as by removing the copyright notice or references to OASIS,  
809 except as needed for the purpose of developing OASIS specifications, in which case the procedures for  
810 copyrights defined in the OASIS Intellectual Property Rights document must be followed, or as required to  
811 translate it into languages other than English.

812 The limited permissions granted above are perpetual and will not be revoked by OASIS or its successors  
813 or assigns.

814 This document and the information contained herein is provided on an "AS IS" basis and OASIS  
815 DISCLAIMS ALL WARRANTIES, EXPRESS OR IMPLIED, INCLUDING BUT NOT LIMITED TO ANY  
816 WARRANTY THAT THE USE OF THE INFORMATION HEREIN WILL NOT INFRINGE ANY RIGHTS OR  
817 ANY IMPLIED WARRANTIES OF MERCHANTABILITY OR FITNESS FOR A PARTICULAR PURPOSE.
